

Business Overview

This project focuses on a company that produces and distributes high-quality nuts and seeds across Saudi Arabia. The Riyadh branch operates through a delivery-based distribution model, covering **6 neighborhoods per week**, with each neighborhood containing approximately **20 grocery stores**.

To better understand customer value and purchasing behavior, the company classifies its stores into three main categories:

Category	Description	Purchase Frequency	Avg Invoice Value (SAR)
A	Large groceries	Weekly	> 500 SAR
B	Medium groceries	Every 2 weeks	200–500 SAR
C	Small groceries	Monthly	< 200 SAR

Current Operations and Business Challenge

Despite having a clear segmentation model, the current operational approach applies the **same weekly visit frequency** to all store categories (A, B, and C) regardless of their purchase frequency and on average, **only ~ 30% of visits result in a sale**. This creates a mismatch between service efforts and actual customer needs, leading to inefficiencies in resource allocation.

The company's goal is to **maximize market coverage, increase sales, and optimize fleet productivity** by aligning visit frequency with customer value.

Category Performance Analysis

Number of stores by category

Number of visits by category

Sales per productive visits & Productivity %

- Most of our visits go to B stores, yet A stores are the main revenue drivers.

Recommended Solution: Smart Visit Frequency Model

Goal: Maximize sales and fleet productivity by matching visit frequency to customer value rather than treating all stores equally.

Group	Old Frequency	New Frequency	Reason	Effect
A	Weekly	Weekly	These stores bring in 849.62 SAR per productive visit, which is the highest return.	No change
B-High	Weekly	Every 2 weeks	Out of 3,077 visits, only 654 resulted in a sale — meaning 2,423 visits didn't lead to anything.	-50% visits
B-Low	Weekly	Monthly		-75% visits
C	Weekly	Monthly	Their productivity looks high, but the actual revenue per productive visit is very low (121.84 SAR). Weekly visits simply don't make financial sense here.	-75% visits

Expected Impact of the Model

This model will do:

Reduce the number of unproductive visits by

These are visits that do not lead to sale and consume fuel, driver hours, and fleet capacity.

Increase sales productivity from

That's an improvement of +11 percentage points, achieved without adding new vans or staff.
